Question 1 of 9

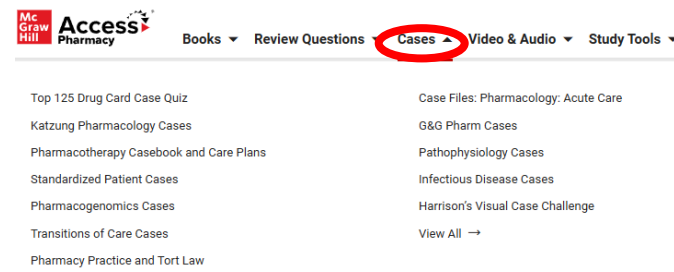

A 52-year-old man presents to the emergency department complaining of the worst headache of his life that is unresolving. It began abruptly 3 days before presentation and is worse with bending over. It rapidly increased in intensity over 30 minutes, but he did not seek medical care at that time. Over the ensuing 72 hours, the headache has persisted although lessened in intensity. He has not lost consciousness and has no other neurologic symptoms. His vision is normal, but he does report that light is painful to his eyes. His past medical history is notable for hypertension, but he takes his medications irregularly. Upon arrival to the emergency department, his initial blood pressure is 232/128 mmHg with a heart rate of 112 beats/min. No nuchal rigidity is present. A head CT shows no acute bleeding and no mass effect. What is the next best step in the management of this patient?

- A. Cerebral angiography
- B. CT angiography
- C. Lumbar puncture
- D. Magnetic resonance angiography
- E. Treat with sumatriptan

Case Approach References Comprehension Questions

Listen

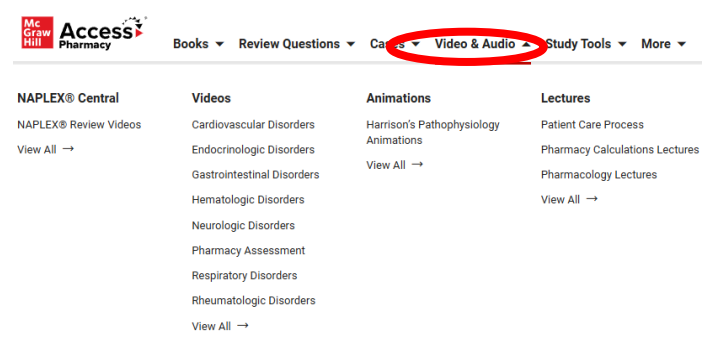

A 45-year-old man presents for the evaluation of weight gain. He has noticed a 20-lb weight gain in the past few months without any change in his diet or activity level. He has started developing “stretch marks” on his abdomen as well. His wife has noted that even his face seems to be “growing fatter.” Review of systems is significant for complaints of fatigue, multiple recent upper respiratory infections, and the development of facial acne. He has no significant medical history and takes no medications. There is a family history of diabetes and hypertension. On examination, his blood pressure is elevated at 165/95 mm Hg, but his other vital signs are normal. His face is plethoric, and he has a small fatty hump developing on his upper back. His abdomen is obese but soft and nontender without masses or fluid. Skin examination is notable for moderate facial acne and multiple violaceous striae on the abdomen. Blood tests show an elevated glucose level of 150 mg/dL, normal electrolytes, and renal function. His thyroid function tests are normal. You suspect idiopathic Cushing disease and order a dexamethasone suppression test to assist with confirming the diagnosis.

**Questions**

Which pituitary hormone stimulates the release of adrenocortical steroids?

What is the major glucocorticoid produced in the adrenal glands?
